

Overcoming the Cloud heterogeneity:

from uniform interfaces and abstract models to multi-cloud platforms

Solutions to overcome Cloud heterogeneity

New: proposal of a research agenda

Cloud heterogeneity

- ▶ **Manifested in**

- ▶ the set of interfaces of the services from different Public Clouds
- ▶ the set of services from the same provider
- ▶ the software stacks
- ▶ the hardware
- ▶ the terms of performance or user quality of experience

- ▶ **Favoring**

- ▶ the Cloud service providers allowing them to be competitive in a very dynamic market especially by exposing unique solutions

- ▶ **Hindering**

- ▶ the interoperability between these services
- ▶ the portability of the applications consuming the services
- ▶ the seamless migration of legacy applications towards Cloud environments

Types of solutions

1. adoption of standards
 - ▶ existing standards
 - ▶ emerging standards
2. usage of intermediary layers
 - ▶ libraries for major programming languages
 - ▶ tools and services
3. adoption of high abstraction levels
 - ▶ semantics
 - ▶ model-driven engineering

Standards and protocols

Type	Examples
Standard	OCCI, OVF, CDMI, CIMI, TOSCA
Reference architecture	IETF, DMTF
Open groups	OCC, GICTF, CSCC, Open Group
Initiatives	ETSI, IEEE, CSA, NIST, OASIS, OW2, SNIA, TM-Forum

Advantages	Limitations
Result of a collective agreement	Not widely adopted
Extract the key actions and characteristics	From the point of view of the providers, hinders diversity
Should be implementable	No. emerging & overlapping standard makes the problem to grow

Open-source libraries

Type	Examples
Libraries	DeltaCloud, fog, jclouds, libcloud, SimpleCloud

Advantages	Disadvantages
Offers an abstraction layer that is simple to use	Usually refers to the common denominator of the Cloud services
Available for major languages	Language dependent
Similarity with major Cloud provider APIs	Adaptors needs to be build for emerging new services
Decouple the application code from the underlying Cloud service	The connected service programming style usually maintained
Adaptors available for major Cloud services	Require Cloud computing knowledge as deployment is usually not supported
	Introduces an overhead compared with the direct connection to Cloud service

Open-source services or tools

Type	Examples
Services/tools	Aoleus, CompatibleOne, Cloudify, ConPaaS, mOSAIC PaaS, Nimbus, OpenNebula, OpenStack, OPTIMIS

Advantages	Disadvantages
Offer unique entry point for application deployment and Cloud resource management	The diversity of deployment services raise also another dimension for the portability
Application deployment can be done by non-Cloud specialists	Manual intervention at deployment phase is usually still needed
Part of them are offering also APIs for programming applications	Life migration is still not possible
Usually it offers support for multiple programming languages	Re-deployments are not automated
Monitoring tools are generate alarms needed to trigger a redeployment	Rely upon adaptors that need to be build for new services or updated when a service version appears

Semantics

Type	Examples
Semantic solution	UCI, mOSAIC Onto & Sem.engine, Cloud4SOA, CPIM/MODAClouds

Advantages	Disadvantages
Offers an abstraction layer that can support various customers	Not widely adopted
Offers viable mechanisms for common understanding of service terminology and actions	The variety of taxonomies and ontologies makes the problem to grow
Allow the annotation of services with quality marks by externals from the provider team	The overhead of semantic processing is not negligible

Model-driven engineering

Type	Examples
Model-driven	MODAClouds, ARTIST, PaaSage

Advantages	Disadvantages
Enhance the abstraction layers with an automation process	Available tools are not yet generating code for various Clouds
Allow a feedback from operational modules to the design modules	The models that are used potentially omit special features of the services

Research agenda – short term

Approach	To Do
Standards	Enhance the number of standard implementations Establish standards for metrics, monitoring, accounting, security Establish standards for machine-readable representations of services, quality, negotiations, processes
Design	Support for decision making for Cloud migration Introduce Modelling-as-a-Service Mechanism for service compositions Build use cases and benchmarks for Cloud portability and interop Define the portability degree
Runtime	Adopt open-source platforms Increase the use of empirical evidence of portability and interop Automate re-deployments

Research agenda – long term

Approach	To Do
Standards	Unified policy of the service level agreements Establish standards for workload and data migration Reference architecture for basic components of software consuming Cloud services
Design	Define re-engineering process for Cloud Mechanisms for code inspections and rewriting Follow a structural approach in the design of the supporting tools Ensure the portability of elasticity rule engines Combine automation with customization
Runtime	Mechanisms for real-time migration Tools for the full service cycle, including Cloud governance Open-source platforms ensuring automated portability or encompassing various approaches

Case study: Multi-Clouds

New: classification

Delivery models for Multiple Clouds

1. Federated Clouds

- ▶ assumes
 - ▶ a formal agreement between the Cloud providers
- ▶ service providers
 - ▶ are sub-contract capacity from other service providers
 - ▶ offer spare capacity to the federated group of providers.
- ▶ the consumer of the service
 - ▶ is not aware of the fact that the Cloud provider he or she pays is using the services of another Cloud provider

2. Multi-Cloud

- ▶ assumes that
 - ▶ there is no priori agreement between the Cloud providers
- ▶ a third party (even the consumer) is responsible for the services
 - ▶ contacts the service providers,
 - ▶ negotiates the terms of service consumption,
 - ▶ monitors the fulfillment of the service level agreements,
 - ▶ triggers the migration of codes, data and networking from one provider to another.

Classification

Examples of open libraries, services, tools

To solve in Multi-Clouds

- ▶ Portability
- ▶ Resource/service selection mechanism and methodology
- ▶ Uniform APIs
- ▶ Search engines
- ▶ Automated deployment
- ▶ Service aggregator
- ▶ Governance
- ▶ ...

Model-driven engineering in Clouds

MODAClouds

MODAClouds (www.modaclouds.eu)

- ▶ Integrated Project n. 318484
- ▶ October 1st 2012 – September 30th 2015

MODAClouds objective

To provide

Methods + decision support system +
+ IDE + runtime environment

to support

- ▶ High-level design
- ▶ Early prototyping
- ▶ Semi-automatic code generation
- ▶ Automatic (re)deployment
- ▶ Monitoring and self-adaptation

of applications on Multi-Clouds
with guaranteed QoS

Multi-Cloud
DevOps Management

MODAClouds Vision

An example

Outputs

Cloud Development Tools

IDE +
MODACloudML (agnostic and QoS ready)
modelling language

Flexible Multi-Cloud Apps Management, Monitoring & Operation Environment

maximizes automation with QoS
Engine, Monitoring, Portability of
underlying infrastructure providers
(IaaS /PaaS)

Decision Support System

is a system on its own enables selection of
provider at development & testing phase;
and adds automation of runtime adaptation

LINE: Performance analyzer

The screenshot shows the Google Code project page for 'line'. The browser address bar displays 'https://code.google.com/p/line/'. The project logo is a blue house with a white 'P' inside, followed by the text 'line' and 'Scalable queueing network model solver'. Below the logo are links for 'Project Home', 'Wiki', 'Issues', and 'Source'. The 'Summary' tab is selected, showing 'Project Information' on the left and a description on the right. The description states that 'line' is a solver for queueing network models based on ordinary differential equations, leveraging mean-field theory. It also mentions that 'line' can compute analytically percentiles of response times for SLA assessment. The 'Releases' section notes that the last and previous releases of LINE can be found [here](#). The 'Documentation' section states that all documentation of Line can be found on [this](#) page. The 'How to cite Line' section provides a reference to a paper by J. F. Perez and G. Casale, 'Assessing SLA compliance from Palladio component models', in *Proceedings of the 2nd MICAS*, 2013. At the bottom right, there are links for 'Terms', 'Privacy', and 'Project Hosting Help', and a note 'Powered by Google Project Hosting'.

Line is a solver for queueing network models based on ordinary differential equations. It leverages the concept of mean-field theory, in which the interactions among a large population of entities are approximated by a single averaged effect. Line can be integrated with the Palladio Bench suite used for performance analysis of Palladio Component Models (PCM).

Compared to existing PCM performance analysers, Line can compute analytically percentiles of response times, which are important for SLA assessment. Furthermore, it can describe uncertainty about an operational environment using a modelling abstraction known as random environment.

Releases

The last and previous releases of LINE can be found [here](#).

Documentation

All the documentation of Line can be found on [this](#) page.
